Study Objectives

There have been several studies suggesting that the prevalence of depression is higher in women than in men. However, the majority of these studies have been cross-sectional and have not taken into account the possibility of a causal relationship between depression and other factors. The purpose of this study was to investigate the prevalence of depression in a community sample of men and women, and to examine the relationship between depression and other factors, such as social support, life events, and personality traits. The study was a longitudinal study, and the prevalence of depression was measured at two time points, 12 months apart. The study was conducted in a community sample of men and women, and the prevalence of depression was measured using a validated measure of depression.

The results of the study showed that the prevalence of depression was higher in women than in men, and that the prevalence of depression was higher in women who had a history of depression than in women who had not. The results also showed that the prevalence of depression was higher in women who had a history of depression than in women who had not, and that the prevalence of depression was higher in women who had a history of depression than in women who had not.

Study Design

The study was a longitudinal study, and the prevalence of depression was measured at two time points, 12 months apart.
