

NAVIDAD, NAVIDADES

Abstract—The purpose of this study was to determine if there were differences in the prevalence of musculoskeletal disorders among different types of workers. Data from the National Longitudinal Study of the Adolescent Health Survey were used to examine the prevalence of musculoskeletal disorders among three groups of workers: full-time employees, part-time employees, and self-employed individuals. The results showed that the prevalence of musculoskeletal disorders was highest among self-employed individuals, followed by full-time employees, and lowest among part-time employees. These findings suggest that self-employment may be associated with a higher risk of developing musculoskeletal disorders.
